	worm disease) by the end of 1995. This article summarizes the recommended strategies for surveillance and interventions in national dracunculiasis eradication programmes. It is based on personal experience with dracunculiasis programmes in Ghana, Nigeria and Pakistan. Three phases are described: estab-

The fundamental difference between an eradication programme and a control programme is critical to understanding the need for some of the strategies recommended in this paper. While a control programme may aim to reduce the incidence of a disease until the disease is no longer a nublic

national task force in order to facilitate mobilization and coordination of the diverse governmental and other agencies whose contributions are needed, such as the government ministries concerned with health, water supplies, and information.

in Pakistan from the beginning of 1990 (6); orientation to the new strategy began in February, two months before the onset of the transmission season. Key elements of this strategy, compared to the previous strategy in Pakistan, were the use of new case investigation forms for VIs and sector supervisors, which ensured that all the appropriate questions were asked and all the prescribed control measures were carried out, whenever a case occurred, and use of revised performance criteria to encourage and monitor the promptness with which these measures it is expected that Pakistan will probably have no more indigenous cases of dracunculiasis.

WHO will expect recently endemic countries to maintain adequate surveillance for at least three years following the last indigenous case, so that they may qualify for certification of elimination. Thus surveillance is also the key to documenting the eradication process.
